Relational Algebra Operations and MapReduce

Relational Algebra Operators

- The relational algebra and the SQL language have many useful operators
 - Selection
 - Projection
 - Union, intersection, and difference
 - Join (see Join design patterns)
 - Aggregations and Group by (see the Summarization design patterns)

Relational Algebra Operators

- The MapReduce paradigm can be used to implement relational operators
 - However, the MapReduce implementation is efficient only when a full scan of the input table(s) is needed
 - i.e., when queries are not selective and process all data
 - Selective queries, which return few tuples/records of the input tables, are usually not efficient when implemented by using a MapReduce approach

Relational Algebra Operators

- Most preprocessing activities involve relational operators
 - E.g., ETL processes in the data warehousing application context

Relations/Tables

- Relations/Tables (also the big ones) can be stored in the HDFS distributed file system
 - They are broken in blocks and spread across the servers of the Hadoop cluster

Relations/Tables

Note

- In relational algebra, relations/tables do not contain duplicate records by definition
- This constraint must be satisfied by both the input and the output relations/tables

- σ_C (R)
 - Applies predicate (condition) C to each record of table R
 - Produces a relation containing only the records that satisfy predicate C
- The selection operator can be implemented by using the filtering pattern

- Map-only job
- Each mapper
 - Analyzes one record at a time of its split
 - If the record satisfies C then it emits a (key,value) pair with key=record and value=null
 - Otherwise, it discards the record

- π_S(R)
 - For each record of table R, keeps only the attributes in S
 - Produces a relation with a schema equal to S (i.e., a relation containing only the attributes in S)
 - Removes duplicates, if any

Duplicated values are removed

Each mapper

- Analyzes one record at a time of its split
 - For each record r in R
 - It selects the values of the attributes in S and constructs a new record r'
 - It emits a (key,value) pair with key=r' and value=null
- Each reducer
 - Emits one (key, value) pair for each input (key, [list of values]) pair with key=r' and value=null

$- R \cup S$

- R and S have the same schema
- Produces a relation with the same schema of R and S
- There is a record t in the output of the union operator for each record t appearing in R or S
- Duplicated records are removed

Mappers

- For each input record t in R, emit one (key, value) pair with key=t and value=null
- For each input record t in S, emit one (key, value) pair with key=t and value=null

Reducers

- Emit one (key, value) pair for each input (key, [list of values]) pair with key=t and value=null
 - i.e., one single copy of each input record is emitted

$R \cap S$

- R and S have the same schema
- Produces a relation with the same schema of R and S
- There is a record t in the output of the intersection operator if and only if t appears in both relations (R and S)

Mappers

- For each input record t in R, emit one (key, value) pair with key=t and value="R"
- For each input record t in S, emit one (key, value) pair with key=t and value="S"

Reducers

- Emit one (key, value) pair with key=t and value=null for each input (key, [list of values]) pair with [list of values] containing two values
 - It happens if and only if both R and S contain t

R - S

- R and S have the same schema
- Produces a relation with the same schema of R and S
- There is a record t in the output of the difference operator if and only if t appears in R but not in S

Mappers

- For each input record t in R, emit one (key, value) pair with key=t and value=name of the relation (i.e., R)
- For each input record t in S, emit one (key, value) pair with key=t and value=name of the relation (i.e., S)
- Two mapper classes are needed
 - One for each relation

Reducers

- Emit one (key, value) pair with key=t and value=null for each input (key, [list of values]) pair with [list of values] containing only the value R
 - It happens if and only if t appears in R but not in S

Join

- The join operators can be implemented by using the Join pattern
 - By using the reduce side or the map side pattern depending on the size of the input relations/tables

Aggregations and Group by

 Aggregations and Group by are implemented by using the Summarization pattern
