- Attributes
- Identifiers
- Generalization
- Documenting E-R Schematics
- UML and E-R

3

3

Life cycle of an information system

Database design

4

4

Database design

- The design of a database is one of the activities of the process of developing an information system
  - must be seen in the broader context of the life cycle of an information system

5

5

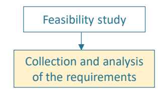
Life cycle of an information system

Determination of the costs of the different alternatives and the priorities for the implementation of each system component

6

Life cycle of an information system

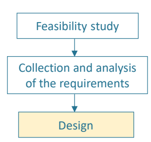
- Definition of the properties and functionalities of the information system
- Requires user interaction
- Produces a comprehensive, but informal, description of the system to be implemented



7

Life cycle of an information system

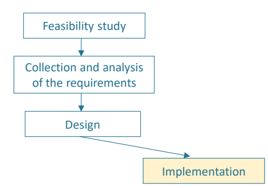
- Divided into data and application design
- Produces formal descriptions



8

Life cycle of an information system

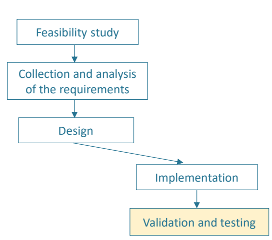
- Implementation of the information system according to the characteristics defined in the design phase



9

Life cycle of an information system

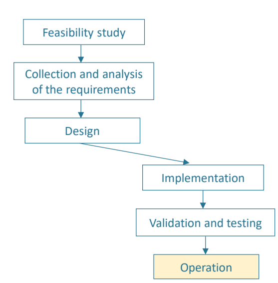
- Verification of the correct functioning and quality of the information system
- It can lead to changes in requirements or design revision



10

Life cycle of an information system

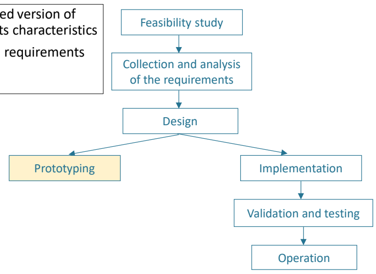
- System operation
- Requires maintenance and managing operations



11

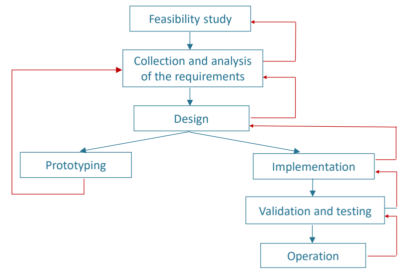
Life cycle of an information system

- Quickly create a simplified version of the system to evaluate its characteristics
- It can lead to changes in requirements or design revision



12

Life cycle of an information system



13

Database design

Database design

14

Database design

- The database is an important component of the entire system
- Data-driven design methodology
  - the design of the database precedes that of the applications that use it
  - greater attention to the design phase than to the other phases

15

Design Methodology

- A design methodology consists of
  - decomposition of the project activity into successive and independent phases
  - strategies to be followed in the various phases and criteria for choosing the best strategy
  - reference models to describe the input and output data of the various phases

16

Properties of the methodology

Generality

- can be used regardless of the problem and the tools available

Quality of the result

- in terms of correctness, completeness and efficiency with respect to the resources used

Ease of use

- of both strategies and reference models

17

Data-driven design

- For databases, methodology based on separating two key decisions
  - *what* to represent in the database
    - conceptual design
  - *how* to represent it
    - logical and physical design

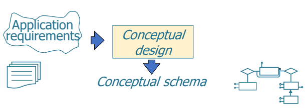
18

Stages of database design

Informal specification of the reality of interest
- Application properties
- Application functionalities

19

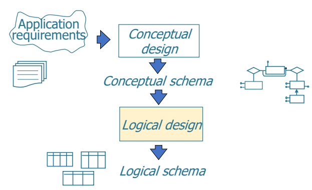
Stages of database design



Representation of informal specifications in the form of a conceptual diagram
- formal and complete description, referring to a conceptual model
- Independent from implementation aspects (data model)
- the aim is to represent the information content of the database

20

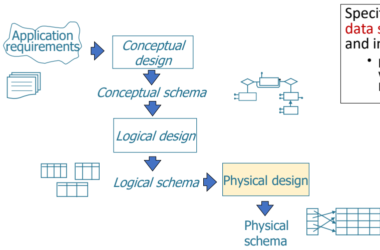
Stages of database design



Translating the conceptual schema into the logical schema
- depends on the chosen data logic model
- takes into account the optimization of data processing operation
- schema quality verified by formal techniques (normalization)

21

Stages of database design



Specification of the physical data storage parameters (File and index organization)
- produces a physical model, which depends on the chosen DBMS

22

Entity-Relationship Model

Database design

23

The E-R (Entity-Relationship) model

- It is the most widely used conceptual model
- Provides constructs to describe specifications about data structure
  - in a simple and understandable way
  - with a graphic formalism
  - independent of the data model, which can be chosen later
- Several variants are available

DBMG 24

24

Main elements of the E-R model

- Entity
- Relations
- Attributes
- Identifiers
- Generalizations and subsets

DBMG 25

25

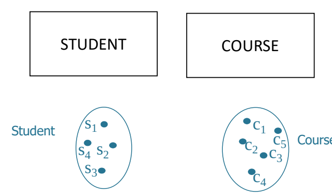
Entity

- It represents classes of real-world objects (people, things, events, ...), which have
  - common Properties
  - autonomous existence
- Examples: Employee, Student, Article
- An occurrence of an entity is an object of the class that the entity represents

26

26

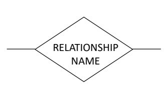
Example of entities



DBMG 27

27

Relationship

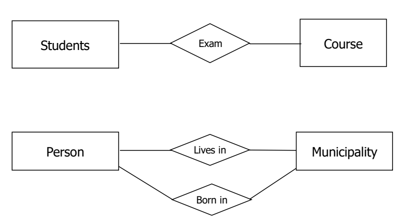


- Represents a logical link between two or more entities
- Examples: exam between student and course, residence between person and municipality
- Not to be confused with the relation of the relational model
  - sometimes referred to as association

28

28

Relationship examples

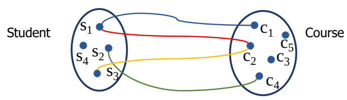


DBMG 29

29

Occurrences of a relationship

- An occurrence of a relationship is an n-tuple (pair in the case of a binary relationship) consisting of occurrences of entities, one for each of the entities involved
- There can be no identical n-tuples



30

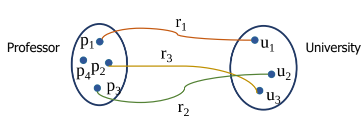
Cardinality of binary relationships

- They are specified for each entity that participates in a relationship
- Describe the minimum and maximum number of occurrences of a relationship in which an occurrence of an entity can participate
  - minimum can be either
    - 0 (optional participation)
    - 1 (participation required)
  - maximum varies between
    - 1 (at most one occurrence)
    - N (arbitrary number of occurrences)

31

Cardinality of binary relationships

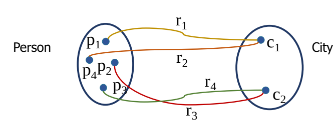
- 1-to-1 relationship



32

Cardinality of binary relationships

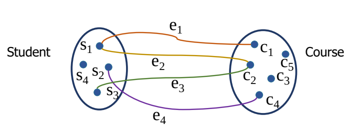
- 1-to-N (many) relationship



33

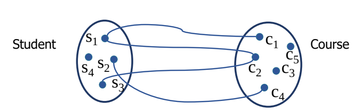
Cardinality of binary relationships

- N-to-N (Many to Many) relationship



34

Limitations of binary relationships

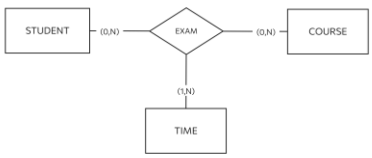


- It is not possible for a student to take the same exam more than once

35

Ternary relationship

- A student may take the same exam more than once at different times.

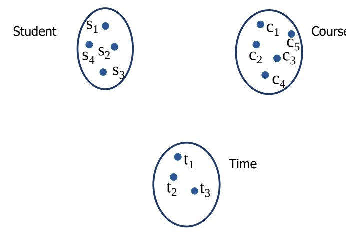


- Example of an instance of the EXAM report

s_1 c_1 t_1
s_1 c_1 t_2
…

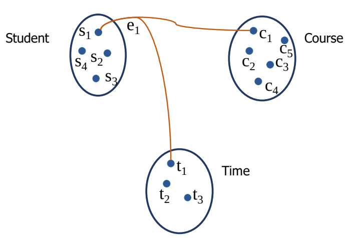
36

Occurrences of a ternary relationship



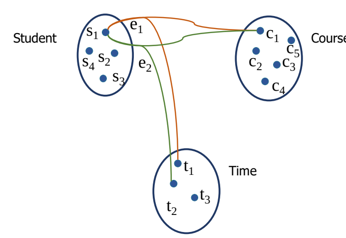
37

Occurrences of a ternary relationship



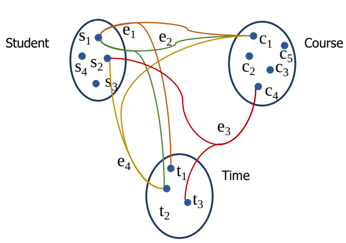
38

Occurrences of a ternary relationship



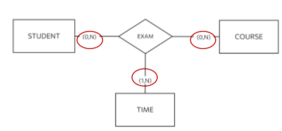
39

Occurrences of a ternary relationship



40

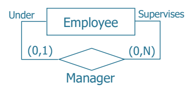
Cardinality of ternary relationships

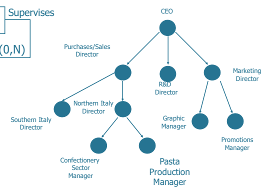


- Minimum cardinalities are rarely 1 for all entities involved in a relationship
- The maximum cardinalities of an n-ary relationship are (practically) always N
  - if the participation of an entity E has a maximum cardinality of 1, it is possible to eliminate the n-ary relationship and associate the entity E with the others by binary relations

41

Recursive relationship



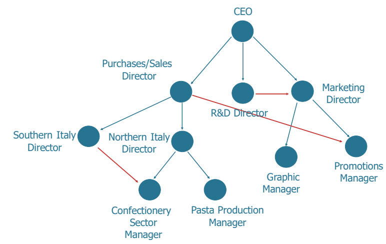


- Relationship between an entity and itself
- If the relationship is not symmetrical, the two roles of the entity must be defined

42

42

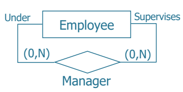
Recursive relationship

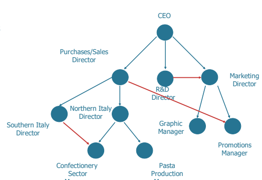


43

43

Recursive relationship



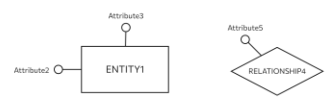


- An employee might have several managers

44

44

Attribute

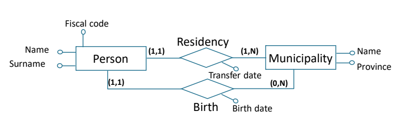


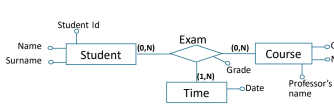
- Describes an elementary property of an entity or relationship
- Examples
  - surname, first name, student ID are attributes that describe the student entity
  - grade is an attribute that describes the exam relationship
- Each attribute is characterized by the domain, the set of admissible values for the attribute

45

45

Examples of attributes

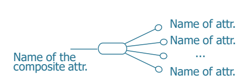




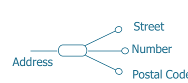
46

46

Composite attribute



- Group of attributes that have closely connected meanings or uses.
- Example:

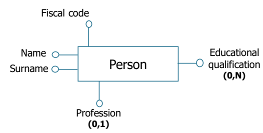


47

47

Cardinality of an attribute

- Can be specified for entity or relationship attributes
- Describes the minimum and maximum number of attribute values associated with an occurrence of an entity or relationship
  - if it is omitted it corresponds to (1,1)
  - minimum 0 corresponds to an attribute that admits a null value
  - maximum N corresponds to an attribute that can have more than one value for the same occurrence (multivalued attribute)



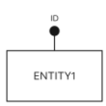
Identifier

- It is specified for each entity
- Describes the concepts (attributes and/or entities) of the schema that allow you to uniquely identify the occurrences of the entities
  - each entity must have at least one identifier
  - there can be more than one appropriate identifier for an entity
- The identifier can be
  - internal or external
  - simple or composite

Internal identifier

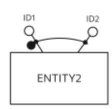
Simple

- consisting of a single attribute



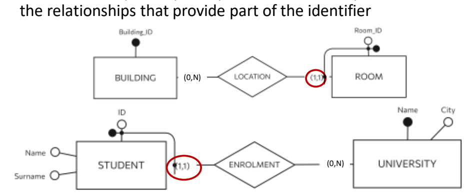
Composite

- consisting of multiple attributes



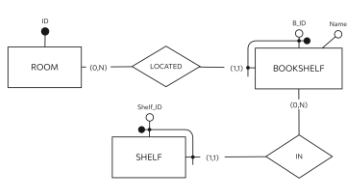
External identifier

- An entity that does not have internal attributes sufficient to define an identifier is called a weak entity
- The weak entity must participate with cardinality (1,1) in each of the relationships that provide part of the identifier



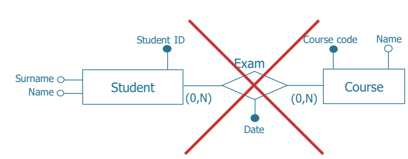
Remarks

- An external identifier can involve an entity that is itself externally identified
  - No identification cycles should be generated



Remarks

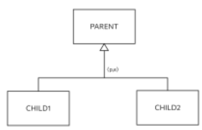
- Relationships do *not* have identifiers



Generalization

It describes a logical link between an entity E and one or more entities $E_1, E_2, \ldots, E_n$, that are particular cases of E.

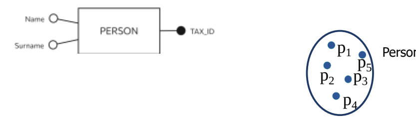
- E is called parent entity, and is a generalization of $E_1, E_2, \ldots, E_n$
- $E_1, E_2, \ldots, E_n$ are called child entities, and are specializations of E



54

54

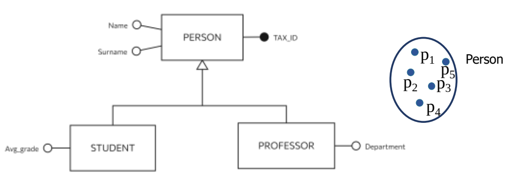
Generalization: example



55

55

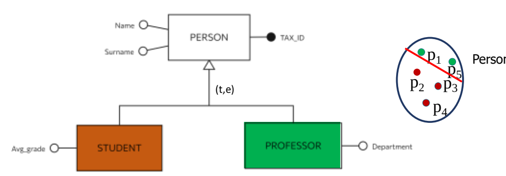
Generalization: example



56

56

Generalization: example



57

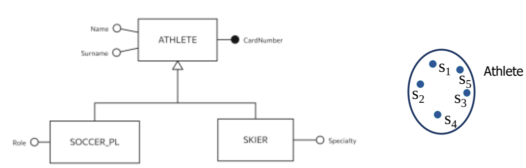
57

Generalization: example

58

58

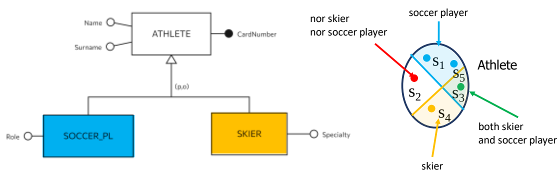
Generalization: example



59

59

Generalization: example



60

Generalization: properties

- Each occurrence of a child entity is also an occurrence of the parent entity
- Each property of the parent entity (attributes, identifiers, relationships, other generalizations) is also a property of each child entity
  - property known as inheritance
- An entity can be involved in multiple different generalizations

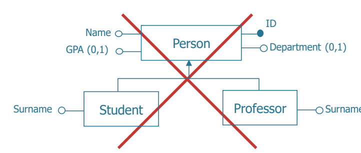
61

Generalization: properties

- Orthogonal characteristics
  - *total* generalization if each instance of the parent entity is an instance of at least one of the child entities, *partial* otherwise.
  - *exclusive* if each instance of the parent entity is at most one instance of one of the child entities, *overlapping* otherwise.

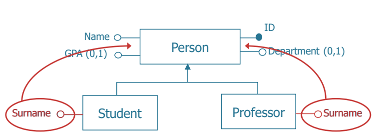
62

Generalization: incorrect example



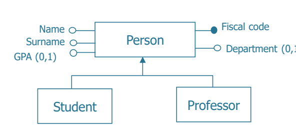
63

Generalization: incorrect example



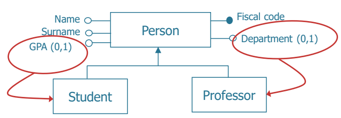
64

Generalization: incorrect example



65

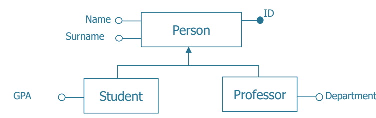
Generalization: incorrect example



DBMG 66

66

Generalization: correct example

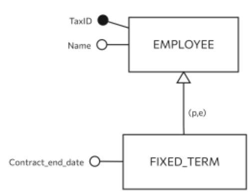


DBMG 67

67

Subset

- Particular case of generalization with only one child entity
  - the generalization is always partial and exclusive



DBMG 68

68

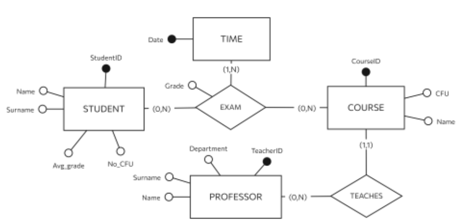
ER Model Documentation

Database design

DBMG 69

69

Documenting E-R models



DBMG 70

70

Documenting E-R models

Data Dictionary

Enrich the E-R schema with natural language descriptions of entities, relationships, and attributes

DBMG 71

71

Data dictionary: example

Entity	Description	Attributes	Identifier
Student	University student	Student ID, Surname, Name, CFU acquired, Grades average	Student ID
Professor	University professor	Professor ID, Department, Surname, Name	Professor ID
Course	Courses offered by the university	Course code, Name, CFU	Course code
Time	Dates on which exams were taken	Date	Date

DBG 72

72

Data dictionary: example

Relationship	Description	Entities involved	Attributes
Exam	It associates a student to the exams taken and memorizes the mark obtained	Student (0,N), Course (0,N), Time (1,N)	Grade
Holder	It associates each course to the professor who teachers the course.	Course (1,1), Professor (0,N)	

DBG 73

73

Documenting E-R models

Data Dictionary

Enrich the E-R schema with natural language descriptions of entities, relationships, and attributes

Data Integrity Constraints

They cannot always be explicitly stated in an E-R scheme

They can be described in natural language

DBG 74

74

Data integrity constraints: examples

Integrity constraints	
RV1	The grade of an exam can only take values between 0 and 30
RV2	Each student cannot pass the same exam twice
RV3	A student may not take more than three exams for the same course during the same academic year

DBG 75

75

Documenting E-R models

Data Dictionary

Enrich the E-R schema with natural language descriptions of entities, relationships, and attributes

Data Integrity Constraints

They cannot always be explicitly stated in an E-R scheme

They can be described in natural language

Data Derivation Rules

Explicitly define that a concept of the schema can be obtained (by inference or arithmetic calculation) from other concepts of the schema

DBG 76

76

Derivation rules: examples

Derivation rules	
RD1	The number of credits acquired by a student is obtained by adding the number of credits of the courses for which the student has passed the exam
RD2	The average mark is obtained by calculating the average of the marks of the exams passed by a student

DBG 77

77

UML vs ER

Database design

78

UML and ER

UML (Unified Modeling Language)

- Modeling a software application
  - structural and behavioural aspects (data, operations, processes and architectures)
- Rich formalism
  - class diagram, actor diagram, sequence diagram, communication diagram, state diagram,...

ER

- Modeling a database
  - structural aspects of an application
- elements tailored to the modelling of a database

79

UML vs ER

- Different formalisms
- The class diagram of an application is different from the E-R schema of the database
- The class diagram, even if designed for different uses, can be adapted for the description of the conceptual design of a database

- Main Differences of UML vs ER
  - no standard notation to define identifiers
  - ability to add notes to comment on diagrams
  - possibility to indicate the direction of navigation of an association (not relevant in the design of a database)

80
