

Relational and Non-relational databases for Big Data

Relational vs Non-relational Databases

«NoSQL» birth

- In 1998 Carlo Strozzi's lightweight, opensource relational database that did not expose the standard SQL interface
- In 2009 Johan Oskarsson's (Last.fm)
 organizes an event to discuss recent
 advances on non-relational databases. A new,
 unique, short hashtag to promote the event
 on Twitter was needed: #NoSQL

Comparison Table-based, each record is a structured storage solutions, e.g., document-based, key-value pairs, graph databases, columnar storage Predefined schema for each table. Schema-less, schema-free, schema changes allowed but usually blocking change is dynamic for each document. (expensive in distributed and live suitable for semi-structured environments) or un-structured data Horizontally scalable, NoSQL Vertically scalable, i.e., typically scaled databases are scaled by increasing the databases servers in the pool of by increasing the power of the hardware resources to reduce the load

Non-Relational databases
Custom query languages, focused on collection of documents, graphs, and other specialized data structures
No standard interfaces to perform complex queries, no joins
Guitable for complex (e.g., hierarchical) Hata, similar to JSON and XML
Examples: MongoDB, BigTable, Redis, Cassandra, HBase and CouchDB
io la

Relational DBMSs

- Pros
 - Work with structured data
 - Support strict ACID transactional consistency
 - Support joins
 - Built-in data integrity
 - Large eco-system
 - Relationships via constraints
 - Limitless indexing
 - Strong SQL
 - OLTP and OLAP
 - Most off-the-shelf applications run on RDBMS

Relational DBMSs

- Cons
 - Do not scale out horizontally (concurrency and data size) – only vertically, unless use sharding
 - Data is normalized, meaning lots of joins, affecting speed
 - Difficulty in working with semi-structured data
 - Schema-on-write

Non-relational/NoSQL DBMSs

- Pros
 - Work with semi-structured data (JSON, XML)
 - Scale out (horizontal scaling parallel query performance, replication)
 - High concurrency, high volume random reads and writes
 - Massive data stores
 - Schema-free, schema-on-read
 - Support records/documents with different fields
 - High availability
 - Speed, due to not having to join tables

Non-relational/NoSQL DBMSs

- Cons
 - Do not support strict ACID transactional consistency
 - Data is denormalized, requiring mass updates (e.g., product name change)
 - Do not have built-in data integrity (must do in code)
 - No relationship enforcement
 - Limited indexing
 - Weak SQL
 - Slow mass updates
 - Use 10-50 more space (replication, denormalized, documents)
 - Difficulty tracking schema changes over time

Data Models

- (Logical) Data model
 - It is a set of constructs for representing the information
- Storage model
 - How the DBMS stores and manipulates the data internally
- A data model is usually independent of the storage model
 - In practice we need at least some insight to achieve good performances

Data Models

- Data model for relational systems
 - Relational model
 - tables, columns and rows
- Data models for NoSQL systems
 - Aggregate models
 - key-value based model
 - Document based model
 - column-family based model
 - Graph-based models

13

Relational Model

- The dominant data model of the last decades was the relational data model
- Relational data model
 - It can be represented as a set of tables
 - Each table has rows, with each row representing an object of interest
 - We describe objects through columns
 - A column may refer to another row in the same or different table (relationship)

14

Relational Model

- The relational model takes the information that we want to store and divides it into tables and tuples (rows)
- However, a tuple is a limited data structure
 - It captures a set of values
 - We can't nest one tuple within another to get nested records
 - Nor we can put a list of values or tuple within another

Aggregate Models

- Data are modeled as units that have a complex structure
 - A more complex structure than just a set of tuples
 - Complex records with
 - Simple fields
 - Lists
 - Maps
 - Records nested inside other records

16

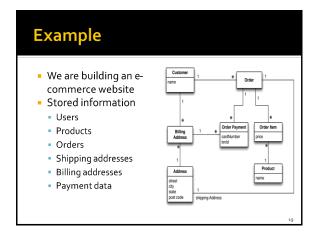

Aggregate Models

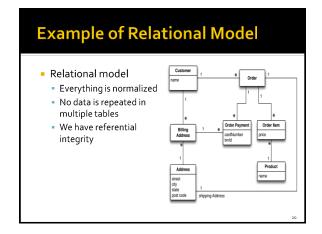

- Aggregate is a term coming from Domain-Driven Design
 - An aggregate is a collection of related objects that we wish to treat as a unit for data manipulation, management, and consistency
- We work with data in terms of aggregates
- We like to update aggregates with atomic operations

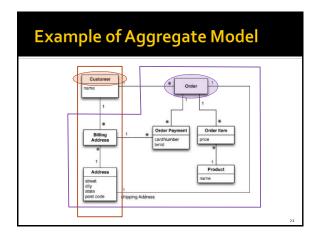

17

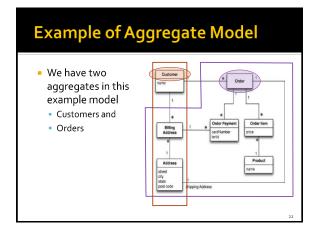

Aggregate Models

- With aggregates we can easier work on a cluster
 - They are "independent" units
- Aggregates are also easier for application programmer to work since solve the impedance mismatch problem of relational databases
 - There is a strict "matching" between the objects used inside programs and the "units/complex records" stored in the databases

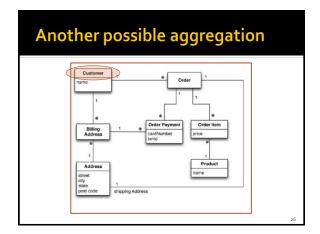

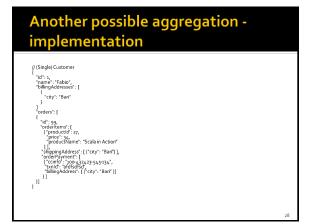

In the example aggregate model there are two "complex types" of records Customer Each customer record contains the customer profile, including his/her billing addresses Order Each order record contains all the data about one order Data are denormalized and some information is replicated

Aggregate implementation

- The solution (data model) is domain-driven
 - The aggregates are related to the expected usage of the data
- In the reported example we suppose to frequently read/write
 - Customer profiles (including shipping addresses)
 - Orders, with all the related information

Another possible aggregation We have one aggregate in this model Customers Customers Customer tank Relief Address Steel Local Andress Steel Lo

Design strategy

- No universal answer for how to draw aggregate boundaries
- It depends entirely on how you tend to manipulate data
 - Accesses on a single order at a time and a single customer at a time
 - First solution
 - Accesses on one customer at a time with all her orders
 - Second solution
- Context-specific
 - Some applications will prefer one or the other

Aggregate Model

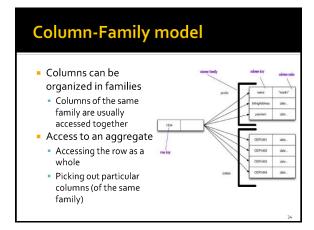

- The focus is on the unit(s) of interaction with the data storage
- Pros:
- It helps greatly when running on a cluster of nodes
 - The data of each "complex record" will be manipulated together, and thus should the stored on the same node
- Cons:
 - An aggregate structure may help with some data interactions but be an obstacle for others

Solutions-based on Aggregate models

- Key-value model
- Column-family based model
- Document-based model

Strongly aggregateoriented
Lots of aggregates
Each aggregate has a key
Data model:
A set of key,value> pairs
Value: an aggregate
instance
The aggregate is opaque
to the database
Just a big blob of mostly
meaningless bit
Access to an aggregate
Lookup based on its key

Strongly aggregateoriented Lots of aggregates Each aggregate has a key Data model: a twolevel map structure: A set of <row-key, aggregate> pairs Each aggregate is a group of pairs <column-key, value>

Properties of Column-Family model

- Operations also allow picking out a particular column
 - get('1234', 'name')
- Each column
 - Has to be part of a single column family
 - Acts as unit for access
- You can add any column to any row, and rows can have very different columns
- You can model a list of items by making each item a separate column

Properties of Column-Family model

- Two ways to look at data
 - Row-oriented
 - Each row is an aggregate
 - Column families represent useful chunks of data within that aggregate
 - Column-oriented
 - Each column family defines a record type
 - Row as the join of records in all column families

Document-based model

- Strongly aggregate-oriented
 - Lots of aggregates
- Each aggregate has a key Data model:
- A set of <key,document> pairs
- Document: an aggregate instance
 Structure of the aggregate
- Limits on what we can place in
- it
 Access to an aggregate
- Queries based on the fields in the aggregate

Key-Value vs Document-based

- Key-value model
 - A key plus a big blob of mostly meaningless bits
 - We can store whatever we like in the aggregate
 - We can only access an aggregate by lookup based on its key
- Document-based model
 - A key plus a structured aggregate
 - More flexibility in access
 - We can submit queries to the database based on the fields in the aggregate
 - We can retrieve part of the aggregate rather than the whole thing
 - Indexes based on the contents of the aggregate

38

Relationships

- Relationship between different aggregates
- Put the ID of one aggregate within the data of the other
- Join: write a program that uses the ID to link data
 - The database is ignorant of the relationship in the data

Key Points

- An aggregate is a collection of data that we interact with as a unit
- Aggregates form the boundaries for ACID operations with the database

40

Key Points

- Aggregates make it easier for the database to manage data storage over clusters
 - Aggregate-oriented databases work best when most data interaction is done with the same aggregate
 - Aggregate-ignorant databases are better when interactions use data organized in many different formations
- Key-value, document, and column-family databases can all be seen as forms of aggregateoriented database

Graph Databases

- Graph databases are motivated by a different frustration with relational databases
 - Complex relationships require complex join
- Goa
 - Capture data consisting of complex relationships
 - Data naturally modeled as graphs
 - Examples
 - Social networks, Web data, product preferences

A graph database | Section | Sectio

Data model of graph databases

- Basic characteristic
- Nodes are connected by edges (also called arcs)
- Beyond this
 - A lot of variation in data models
 - Neo4J stores Java objects as nodes and edges in a schemaless fashion
 - InfiniteGraphstores Java objects, which are subclasses of built-in types, as nodes and edges.
 - FlockDB is simply nodes and edges with no mechanism for additional attributes

6.6

Data model of graph databases

- Queries
 - Navigation through the network of edges
 - You do need a starting place
 - Nodes can be indexed by an attribute such as ID

45

Graph vs Relational databases

- Relational databases
 - Implement relationships using foreign keys
 - Joins require to navigate around and can get quite expensive
- Graph databases
 - Make traversal along the relationships very cheap
- Performance is better for highly connected data
- Shift most of the work from query time to insert time
- Good when querying performance is more important than insert speed

Graph vs Aggregate-oriented databases

- Very different data models
- Aggregate-oriented databases
 - Distributed across clusters
 - Simple query languages
 - No ACID guarantees
- Graph databases
 - More likely to run on a single server
 - Graph-based query languages
 - Transactions maintain consistency over multiple nodes and edges

Some NoSQL databases

- Key-value databases
 - Redis, Riak, Memcached, ..
- Column-family databases
 - Cassandra, HBase, Hypertable, Amazon DynamoDB, ..
- Document databases
 - MongoDB, CouchDB, RavenDB, ...
- Graph databases
 - Neo4J, Infinite Graph, OrientDB, ...
