

Big data: architectures and data analytics

RDD-based programming

Transformations on two Pair RDDs

Transformations on pairs of Pair RDDs

- Spark supports also some transformations on two PairRDDs
 - SubtractByKey, join, coGroup, etc.

SubtractByKey transformation

SubtractByKey transformation

- Goal
 - Create a new PairRDD containing only the pairs of the input PairRDD associated with a key that is not appearing as key in the pairs of the other PairRDD
 - The data type of the new PairRDD is the same of the “input” PairRDD
 - The input PairRDD and the other PairRDD must have the same type of keys
 - The data type of the values can be different

SubtractByKey transformation

- Method

- The subtractByKey transformation is based on the `JavaPairRDD<K,V>` `subtractByKey(JavaPairRDD<K,U> other)` method of the `JavaPairRDD<K,V>` class

7

SubtractByKey transformation: Example

- Create two JavaPairRDDs from two local Java lists
 - First list – Profiles of the users of a blog (username, age)
 - `{("PaoloG", 40), ("Giorgio", 22), ("PaoloB", 35)}`
 - Second list – Banned users (username, motivation)
 - `{("PaoloB", "spam"), ("Giorgio", "Vandalism")}`
- Create a new PairRDD containing only the profiles of the non-banned users

8

SubtractByKey transformation: Example

```
// Create the first local Java collection
ArrayList<Tuple2<String, Integer>> profiles =
    new ArrayList<Tuple2<String, Integer>>();

Tuple2<String, Integer> localPair;
localPair = new Tuple2<String, Integer>("PaoloG", 40);
profiles.add(localPair);

localPair = new Tuple2<String, Integer>("Giorgio", 22);
profiles.add(localPair);

localPair = new Tuple2<String, Integer>("PaoloB", 35);
profiles.add(localPair);

// Create the JavaPairRDD from the local collection
JavaPairRDD<String, Integer> profilesPairRDD = sc.parallelizePairs(profiles);
```

9

SubtractByKey transformation: Example

```
// Create the second local Java collection
ArrayList<Tuple2<String, String>> banned =
    new ArrayList<Tuple2<String, String>>();
Tuple2<String, String> localPair2;
localPair2 = new Tuple2<String, String>("PaoloB", "spam");
banned.add(localPair2);

localPair2 = new Tuple2<String, String>("Giorgio", "Vandalism");
banned.add(localPair2);
// Create the JavaPairRDD from the local collection
JavaPairRDD<String, String> bannedPairRDD = sc.parallelizePairs(banned);

// Select the profiles of the “good” users
JavaPairRDD<String, Integer> selectedUsersPairRDD =
    profilesPairRDD.subtractByKey(bannedPairRDD);
```

10

Join transformation

Join transformation

■ Goal

- Join the key-value pairs of two PairRDDs based on the value of the key of the pairs
 - Each pair of the input PairRDD is combined with all the pairs of the other PairRDD with the same key
 - The new PairRDD
 - Has the same key data type of the "input" PairRDDs
 - Has a tuple as value (the pair of values of the two joined input pairs)
 - The input PairRDD and the other PairRDD
 - Must have the same type of keys
 - But the data types of the values can be different

Join transformation

- Method
 - The join transformation is based on the `JavaPairRDD <K, Tuple2<V,U>>` `join(JavaPairRDD<K,U>)` method of the `JavaPairRDD<K,V>` class

13

Join transformation: Example

- Create two JavaPairRDD from two local Java lists
 - First list – List of questions (QuestionId, Text of the question)
 - `{(1, "What is .. ?"), (2, "Who is ..?")}`
 - Second list – List of answers (QuestionId, Text of the answer)
 - `{(1, "It is a car"), (1, "It is a byke"), (2, "She is Jenny")}`
- Create a new PairRDD associating each question with its answers
 - One pair for each possible pair question - answer

14

Join transformation: Example

```
// Create the first local Java collection
ArrayList<Tuple2<Integer, String>> questions=
    new ArrayList<Tuple2<Integer, String>>();

Tuple2<Integer, String> localPair;
localPair = new Tuple2<Integer, String>(1, "What is .. ?");
questions.add(localPair);

localPair = new Tuple2<Integer, String>(2, "Who is .. ?");
questions.add(localPair);

// Create the JavaPairRDD from the local collection
JavaPairRDD<Integer, String> questionsPairRDD =
    sc.parallelizePairs(questions);
```

15

Join transformation: Example

```
// Create the second local Java collection
ArrayList<Tuple2<Integer, String>> answers =
    new ArrayList<Tuple2<Integer, String>>();

Tuple2<Integer, String> localPair2;
localPair2 = new Tuple2<Integer, String>(1, "It is a car");
answers.add(localPair2);

localPair2 = new Tuple2<Integer, String>(1, "It is a byke");
answers.add(localPair2);

localPair2 = new Tuple2<Integer, String>(2, "She is Jenny");
answers.add(localPair2);

// Create the JavaPairRDD from the local collection
JavaPairRDD<Integer, String> answersPairRDD = sc.parallelizePairs(answers);
```

16

Join transformation: Example

```
// Join questions with answers  
JavaPairRDD<Integer, Tuple2<String, String>> joinPairRDD =  
    questionsPairRDD.join(answersPairRDD);
```

17

Join transformation: Example

```
// Join questions with answers  
JavaPairRDD<Integer, Tuple2<String, String>> joinPairRDD =  
    questionsPairRDD.join(answersPairRDD);
```

Note that the value part is a Tuple2 element (i.e., also the value is a pair).

18

CoGroup transformation

Cogroup transformation

- Goal
 - Associated each key **k** of the input PairRDDs with
 - The list of values associated with **k** in the input PairRDD
 - And the list of values associated with **k** in the other PairRDD
 - The new PairRDD
 - Has the same key data type of the “input” PairRDDs
 - Has a tuple as value (the two lists of values of the two input pairs)
 - The input PairRDD and the other PairRDD
 - Must have the same type of keys
 - But the data types of the values can be different

Cogroup transformation

- Method

- The cogroup transformation is based on the
JavaPairRDD <K, Tuple2<Iterable<V>, Iterable<U>>> cogroup(JavaPairRDD<K, U>)
method of the **JavaPairRDD<K, V>** class

21

Cogroup transformation: Example

- Create two JavaPairRDD from two local Java lists
 - First list – List of liked movies (userId, likedMovies)
 - {(1, "Star Trek"), (1, "Forrest Gump"), (2, "Forrest Gump")}
 - Second list – List of liked directors (userId, likedDirector)
 - {(1, "Woody Allen"), (2, "Quentin Tarantino"),
(2, "Alfred Hitchcock")}
- Create a new PairRDD containing one pair for each userId (key) associated with
 - The list of liked movies
 - The list of liked directors

22

Cogroup transformation: Example

- Inputs

- {(1, "Star Trek"), (1, "Forrest Gump"), (2, "Forrest Gump")}
- {(1, "Woody Allen"), (2, "Quentin Tarantino"), (2, "Alfred Hitchcock")}

- Output

- (1, ("Star Trek", "Forrest Gump"), ["Woody Allen"])
- (2, ("Forrest Gump"), ["Quentin Tarantino", "Alfred Hitchcock"])

23

Cogroup transformation: Example

```
// Create the first local Java collection
ArrayList<Tuple2<Integer, String>> movies=
    new ArrayList<Tuple2<Integer, String>>();

Tuple2<Integer, String> localPair;
localPair = new Tuple2<Integer, String>(1, "Star Trek");
movies.add(localPair);

localPair = new Tuple2<Integer, String>(1, "Forrest Gump");
movies.add(localPair);

localPair = new Tuple2<Integer, String>(2, "Forrest Gump");
movies.add(localPair);

// Create the JavaPairRDD from the local collection
JavaPairRDD<Integer, String> moviesPairRDD = sc.parallelizePairs(movies);
```

24

Cogroup transformation: Example

```
// Create the second local Java collection
ArrayList<Tuple2<Integer, String>> directors =
    new ArrayList<Tuple2<Integer, String>>();
Tuple2<Integer, String> localPair2;
localPair2 = new Tuple2<Integer, String>(1, "Woody Allen");
directors.add(localPair2);

localPair2 = new Tuple2<Integer, String>(2, "Quentin Tarantino");
directors.add(localPair2);

localPair2 = new Tuple2<Integer, String>(2, "Alfred Hitchcock");
directors.add(localPair2);

// Create the JavaPairRDD from the local collection
JavaPairRDD<Integer, String> directorsPairRDD=
    sc.parallelizePairs(directors);
```

25

Cogroup transformation: Example

```
// Cogroup movies and directors per user
JavaPairRDD<Integer, Tuple2<Iterable<String>, Iterable<String>>>
    cogroupPairRDD = moviesPairRDD.cogroup(directorsPairRDD);
```

26

Cogroup transformation: Example

```
// Cogroup movies and directors per user  
JavaPairRDD<Integer, Tuple2<Iterable<String>, Iterable<String>>>  
cogroupPairRDD = moviesPairRDD.cogroup(directorsPairRDD);
```

Note that the value part is a Tuple2 element containing two "lists":
-The first part of the Tuple2 element (._1()) contains the "list" of movies liked by the user
-The second part (._2()) contains the "list" of directors liked by the user

27

Transformations on two PairRDDs: Summary

Transformations on two Pair RDDs: Summary

- All the examples reported in the following tables are applied on the following two PairRDDs
 - `inputRDD1{("k1", 2), ("k3", 4), ("k3", 6)}`
 - `inputRDD2 {("k3", 9)}`

29

Transformations on two Pair RDDs: Summary

Transformation	Purpose	Example	Result
<code>JavaPairRDD<K,V> subtractByKey(JavaPairRDD<K,U>)</code>	Return a new PairRDD where the pairs associated with a key appearing only in the "input" PairRDD and not in the one passed as parameter. The values are not considered to take the decision.	<code>inputRDD1. subtract (inputRDD2)</code>	<code>{("K1",2)}</code>
<code>JavaPairRDD <K, Tuple2<V,U>> join(JavaPairRDD<K,U>)</code>	Return a new PairRDD corresponding to join of the two PairRDDs. The join is based in the value of the key.	<code>inputRDD1.join (inputRDD2)</code>	<code>{("k3", (4,9)), ("k3", (6,9))}</code>

30

Transformations on two Pair RDDs: Summary

Transformation	Purpose	Example	Result
JavaPairRDD<K, Tuple2<Iterable<V>, Iterable<U>>> cogroup(JavaPairRDD<K,U>)	For each key k in one of the two PairRDDs, return a pair (k, tuple), where tuple contains the list of values of the first PairRDD with key k in the first element of the tuple and the list of values of the second PairRDD with key k in the second element of the tuple.	inputRDD1.cogroup(inputRDD2)	{"K1", ([2], [])), ("K3", ([4, 6], [9]))}

31

Actions on Pair RDDs

Actions on Pair RDDs

- Spark supports also some specific actions on PairRDDs
 - countByKey, collectAsMap, lookup

33

CountByKey action

CountByKey action

- Goal

- The countByKey action returns a local Java Map object containing the information about the number of elements associated with each key in the PairRDD
 - i.e., the number of times each key occurs in the PairRDD
- **Pay attention to the number of distinct keys of the PairRDD**
- **If the number of distinct keys is large, the result of the action cannot be stored in a local variable of the Driver**

35

CountByKey action

- Method

- The countByKey action is based on the `java.util.Map<K, java.lang.Object>` `countByKey()` method of the `JavaPairRDD<K,V>` class
 - The values of the returned `java.util.Map` are returned as “generic” `java.lang.Object`
 - However, they are `java.lang.Long` objects

36

CountByKey action: Example 1

- Create a JavaPairRDD from the following Java list
 - {("Forrest Gump", 4), ("Star Trek", 5), ("Forrest Gump", 3)}
 - Each pair contains a movie and the rating given by someone to the movie
- Compute the number of ratings for each movie

37

CountByKey action: Example 1

```
// Create the local Java collection
ArrayList<Tuple2<String, Integer>> movieRating=
    new ArrayList<Tuple2<String, Integer>>();

Tuple2<String, Integer> localPair;
localPair = new Tuple2<String, Integer>("Forrest Gump", 4);
movieRating.add(localPair);

localPair = new Tuple2<String, Integer>("Star Trek", 5);
movieRating.add(localPair);

localPair = new Tuple2<String, Integer>("Forrest Gump", 3);
movieRating.add(localPair);
```

38

CountByKey action: Example 1

```
// Create the JavaPairRDD from the local collection  
JavaPairRDD<String, Integer> movieRatingRDD =  
    sc.parallelizePairs(movieRating);  
  
// Compute the number of rating for each movie  
java.util.Map<String, java.lang.Object> movieNumRatings =  
    movieRatingRDD.countByKey();  
  
// Print the result on the standard output  
System.out.println(movieNumRatings);
```

39

CountByKey action: Example 1

```
// Create the JavaPairRDD from the local collection  
JavaPairRDD<String, Integer> movieRatingRDD =  
    sc.parallelizePairs(movieRating);  
  
// Compute the number of rating for each movie  
java.util.Map<String, java.lang.Object> movieNumRatings =  
    movieRatingRDD.countByKey();
```

// Pr
System.out.println(movieNumRatings);

Pay attention to the size of the returned map (i.e., the number of distinct movies in this case).

40

CollectAsMap action

CollectAsMap action

- Goal
 - The collectAsMap action returns a local Java `java.util.Map<K,V>` containing the same pairs of the considered PairRDD
 - **Pay attention to the size of the PairRDD**
- Method
 - The collectAsMap action is based on the `java.util.Map<K,V> collectAsMap()` method of the `JavaPairRDD<K,V>` class

CollectAsMap action

- Pay attention that the **collectAsMap** action returns a `java.util.Map` object
- A Map cannot contain duplicate keys
 - Each key can map to at most one value
 - If the “input” PairRDD contains more than one pair with the same key, only one of those pairs is stored in the returned local Java Map
 - Usually, the last one in the PairRDD
- Use `collectAsMap` only if you are sure that each key appears only once in the PairRDD

43

CollectAsMap action: Example 1

- Create a JavaPairRDD from the following Java list
 - `{("User1", "Paolo"), ("User2", "Luca"), ("User3", "Daniele")}`
 - Each pair contains a userId and the name of the user
- Retrieve the pairs of the created PairRDD and store them in a local Java Map that is instantiated in the Driver

44

CollectAsMap action: Example 1

```
// Create the local Java collection
ArrayList<Tuple2<String, String>> users=
    new ArrayList<Tuple2<String, String>>();

Tuple2<String, String> localPair;
localPair=new Tuple2<String, String>("User1", "Paolo");
users.add(localPair);

localPair=new Tuple2<String, String>("User2", "Luca");
users.add(localPair);

localPair=new Tuple2<String, String>("User3", "Daniele");
users.add(localPair);
```

45

CollectAsMap action: Example 1

```
// Create the JavaPairRDD from the local collection
JavaPairRDD<String, String> usersRDD =
    sc.parallelizePairs(users);

// Retrieve the content of usersRDD and store it in a local Java Map
java.util.Map<String, String> retrievedPairs = usersRDD.collectAsMap();

// Print the result on the standard output
System.out.println(retrievedPairs);
```

46

CollectAsMap action: Example 1

```
// Create the JavaPairRDD from the local collection  
JavaPairRDD<String, String> usersRDD =  
    sc.parallelizePairs(users);  
  
// Retrieve the content of usersRDD and store it in a local Java Map  
java.util.Map<String, String> retrievedPairs = usersRDD.collectAsMap();  
  
// Print the Pay attention to the size of the returned map  
System.out.println(retrievedPairs);
```

47

Lookup action

Lookup action

- Goal

- The lookup(`k`) action returns a local Java `java.util.List<V>` containing the values of the pairs of the PairRDD associated with the key `k` specified as parameter

- Method

- The lookup action is based on the `java.util.List<V> lookup(K key)` method of the `JavaPairRDD<K,V>` class

49

Lookup action: Example 1

- Create a JavaPairRDD from the following Java list
 - `{"Forrest Gump", 4}, {"Star Trek", 5}, {"Forrest Gump", 3}`
 - Each pair contains a movie and the rating given by someone to the movie
- Retrieve the ratings associated with the movie “Forrest Gump” and store them in a local Java list in the Driver

50

Lookup action: Example 1

```
// Create the local Java collection
ArrayList<Tuple2<String, Integer>> movieRating=
    new ArrayList<Tuple2<String, Integer>>();

Tuple2<String, Integer> localPair;
localPair = new Tuple2<String, Integer>("Forrest Gump", 4);
movieRating.add(localPair);

localPair = new Tuple2<String, Integer>("Star Trek", 5);
movieRating.add(localPair);

localPair = new Tuple2<String, Integer>("Forrest Gump", 3);
movieRating.add(localPair);
```

51

Lookup action: Example 1

```
// Create the JavaPairRDD from the local collection
JavaPairRDD<String, Integer> movieRatingRDD =
    sc.parallelizePairs(movieRating);

// Select the ratings associated with "Forrest Gump"
java.util.List<Integer> movieRatings =
    movieRatingRDD.lookup("Forrest Gump");

// Print the result on the standard output
System.out.println(movieRatings);
```

52

Lookup action: Example 1

```
// Create the JavaPairRDD from the local collection  
JavaPairRDD<String, Integer> movieRatingRDD =  
    sc.parallelizePairs(movieRating);  
  
// Select the ratings associated with "Forrest Gump"  
java.util.List<Integer> movieRatings =  
    movieRatingRDD.lookup("Forrest Gump");  
  
// Pr  
System.out.println(movieRatings);  
  
// Pay attention to the size of the returned list (i.e., the  
// number of ratings associated with "Forrest Gump" in this  
// case).
```

53

Actions on PairRDDs: Summary

Actions on PairRDDs: Summary

- All the examples reported in the following tables are applied on the following PairRDD
 - {("k1", 2), ("k3", 4), ("k3", 6)}

55

Actions on PairRDDs: Summary

Transformation	Purpose	Example	Result
java.util.Map<K,java.lang.Object> countByKey()	Return a local Java java.util.Map containing the number of elements in the input PairRDD for each key of the input PairRDD.	inputRDD.countByKey()	{("K1",1), ("K3",2)}
java.util.Map<K,V> collectAsMap()	Return a local Java java.util.Map containing the pairs of the input PairRDD	inputRDD.collectAsMap() Or Depending on the order of the pairs in the PairRDD	{("k1", 2), ("k3", 6)} Or {"k1", 2}, {"k3", 4}

56

Actions on PairRDDs: Summary

Transformation	Purpose	Example	Result
java.util.List<V> lookup(K key)	Return a local Java java.util.List containing all the values associated with the key specified as parameter	inputRDD.lookup("k3")	{4, 6}
