- Guidelines in writing triggers in Oracle
- Trigger Design
Active Database Systems
Active database systems

Traditional DBMS operation is *passive*

- Queries and updates are explicitly requested by users
- The knowledge of processes operating on data is typically embedded into applications

Active database systems

- Reactivity is a service provided by a normal DBMS
- Reactivity *monitors* specific database events and *triggers* actions in response
Active database systems

- Reactivity is provided by automatically executing rules
- Rules are in the form
  - Event
  - Condition
  - Action
- Also called active or ECA rules
Active rules

△ Event
  - Database modification operation

△ Condition
  - Predicate on the database state
  - If the condition is true, the action is executed

△ Action
  - Sequence of SQL instructions or application procedure
Rule engine

- Component of the DBMS, in charge of:
  - Tracking events
  - Executing rules when appropriate
    - based on the execution strategy of the DBMS

- Rule execution is interleaved with traditional transaction execution
The active rule manages reorder in an inventory stock
- when the stocked quantity of a product goes below a given threshold
- a new order for the product should be issued

Event
- Update of the quantity on hand for product x
- Insert of a new product x
The active rule manages reorder in an inventory stock

- when the stocked quantity of a product goes below a given threshold
- a new order for the product should be issued

**Condition**

- The quantity on hand is below a given threshold
  
  *and* there are no pending orders for product x

**Action**

- Issue an order with given reorder quantity for product x
Applications of active rules

- Internal applications
  - maintenance of complex integrity constraints
  - replication management
  - materialized view maintenance

- Business Rules
  - Incorporate into the DBMS application knowledge
    - E.g., reorder rule

- Alerters
  - widely used for notification
Triggers

- Commercial products implement active rules by means of *triggers*

- SQL provides instructions for defining triggers
  - Triggers are defined by means of the DDL instruction `CREATE TRIGGER`

- Trigger syntax and semantics are covered in the SQL3 standard
  - Some commercial products implement different features with respect to the standard
Trigger structure

- Event
  - Insert, delete, update of a table
  - Each trigger can only monitor events on a single table

- Condition
  - SQL predicate (it is optional)

- Action
  - Sequence of SQL instructions
  - Proprietary programming language blocks
    - e.g. Oracle PL/SQL
  - Java block
Execution process

When the events take place [triggering]
If the condition is true [evaluation]
Then the action is executed [execution]

▷ Seems very simple but...

- Execution modes
- Execution granularity
Immediate
- The trigger is executed *immediately before* or *after* the triggering statement

Deferred
- The trigger is executed *immediately before commit*

Only the immediate option is available in commercial systems
Execution granularity

 Tuple (or row level)
  - One separate execution of the trigger *for each* tuple affected by the triggering statement

 Statement
  - One single trigger execution *for all tuples* affected by the triggering statement
Granularity example

Table T

<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>5</td>
</tr>
<tr>
<td>2</td>
<td>9</td>
</tr>
<tr>
<td>8</td>
<td>20</td>
</tr>
</tbody>
</table>

Transaction statement

```
UPDATE T
SET A = A + 1
WHERE B < 10;
```

Trigger execution

- A row level trigger executes twice
- A statement level trigger executes once
Database Management Systems

Oracle Triggers
CREATE TRIGGER  TriggerName
Mode Event {OR Event }
ON  TargetTable
[[ REFERENCING  ReferenceName]]
FOR EACH ROW
[WHEN  Predicate]]
PL/SQL Block
Trigger syntax

CREATE TRIGGER `TriggerName`

`Mode Event {OR Event}`

ON `TargetTable`

[[ REFERENCING `ReferenceName`]]

FOR EACH ROW

[WHEN `Predicate`]]

PL/SQL Block

⇒ `Mode` is BEFORE or AFTER

● Also INSTEAD OF but it should be avoided
CREATE TRIGGER  TriggerName  
Mode Event {OR  Event }  
ON  TargetTable  
[[ REFERENCING  ReferenceName]]  
FOR EACH ROW  
[WHEN  Predicate]]  
PL/SQL  Block

Event ON  TargetTable  is 
- INSERT  
- DELETE  
- UPDATE [OF  ColumnName]
CREATE TRIGGER  TriggerName
Mode Event {OR Event }
ON  TargetTable
[[ REFERENCING  ReferenceName]]
FOR EACH ROW
[WHEN  Predicate]]
PL/SQL Block

▷ FOR EACH ROW specifies row level execution semantics
● If omitted, the execution semantics is statement level
Trigger syntax

- CREATE TRIGGER `TriggerName`
- `Mode Event {OR Event}`
- ON `TargetTable`
- `[[ REFERENCING ReferenceName]`
- **FOR EACH ROW**
- `[[WHEN Predicate]]`
- PL/SQL Block

The old and new states of the row triggering a *row level* trigger may be accessed by means of the
- OLD.`ColumnName` variable
- NEW.`ColumnName` variable
CREATE TRIGGER  TriggerName  
Mode Event {OR Event }
ON  TargetTable 
[[ REFERENCING  ReferenceName]]
FOR EACH ROW
[WHEN  Predicate]]
PL/SQL Block

➢ To rename the state variables

▪ REFERENCING OLD AS  OldVariableName
▪ similarly for NEW
Trigger syntax

CREATE TRIGGER  *TriggerName*
*Mode Event {OR Event}*
ON  *TargetTable*
[[ REFERENCING  *ReferenceName*]]
FOR EACH ROW
[WHEN  *Predicate*]]
PL/SQL Block

⇒ Only for row level execution semantics (i.e., FOR EACH ROW)

- A condition may be optionally specified
- The old and new state variables may be accessed
**Trigger syntax**

```sql
CREATE TRIGGER TriggerName
Mode Event {OR Event }
ON TargetTable
[[ REFERENCING ReferenceName]]
FOR EACH ROW
[WHEN Predicate]]
PL/SQL Block
```

△ The action is
- a sequence of SQL instructions
- a PL/SQL block

△ *No* transactional and DDL instructions
**Trigger semantics**

- **Execution modes**
  - immediate before
  - immediate after

- **Granularity is**
  - row (tuple)
  - statement

- Execution is triggered by insert, delete, or update statements in a transaction
Execution algorithm

1. Before statement triggers are executed
2. For each tuple in TargetTable affected by the triggering statement
   a) Before row triggers are executed
   b) The triggering statement is executed
      + integrity constraints are checked on tuples
   c) After row triggers are executed
3. Integrity constraints on tables are checked
4. After statement triggers are executed
The execution order for triggers with the same event, mode and granularity is not specified.
- It is a source of non-determinism.

When an error occurs:
- Rollback of all operations performed by the triggers.
- Rollback of the triggering statement in the triggering transaction.
Non termination

- Trigger execution may activate other triggers
  - Cascaded trigger activation may lead to non termination of trigger execution
- A maximum length for the cascading trigger execution may be set
  - default = 32 triggers
- If the maximum is exceeded
  - an execution error is returned
A *mutating table* is the table modified by the statement (i.e., event) triggering the trigger.

The mutating table:
- *cannot* be accessed in row level triggers
- *may only* be accessed in statement triggers

Limited access on mutating tables only characterizes Oracle applications:
- accessing mutating tables is *always* allowed in SQL3
Example

- Trigger to manage reorder in an inventory stock
  - when the stocked quantity of a product goes below a given threshold
  - a new order for the product should be issued

- The following database schema is given
  - Inventory (Part#, QtyOnHand, ThresholdQty, ReorderQty)
  - PendingOrders(Part#, OrderDate, OrderedQty)
Example

- Trigger to manage reorder in an inventory stock
  - when the stocked quantity of a product goes below a given threshold
  - a new order for the product should be issued

- Event
  - Update of the quantity on hand for product x
  - Insert of a new product x

- Execution semantics
  - After the modification event
  - Separate execution for each row of the Inventory table
CREATE TRIGGER Reorder
AFTER UPDATE OF QtyOnHand OR INSERT ON Inventory
FOR EACH ROW
Example

Trigger to manage reorder in an inventory stock
- when the stocked quantity of a product goes below a given threshold
- a new order for the product should be issued

Condition
- The quantity on hand is below a given threshold
CREATE TRIGGER Reorder
AFTER UPDATE OF QtyOnHand OR INSERT ON Inventory
FOR EACH ROW
WHEN (NEW.QtyOnHand < NEW.ThresholdQty)
Example

- **Trigger to manage reorder in an inventory stock**
  - when the stocked quantity of a product goes below a given threshold
  - a new order for the product should be issued

- **Condition**
  - The quantity on hand is below a given threshold
    - *and* there are no pending orders for product x
      - This part cannot be introduced into the WHEN clause

- **Action**
  - Issue an order with given reorder quantity for product x
DECLARE
    N number;
BEGIN
    select count(*) into N
    from PendingOrders
    where Part# = :NEW.Part#;
    If (N=0) then
        insert into PendingOrders(Part#,OrderedQty,OrderDate)
        values (:NEW.Part#, :NEW.ReorderQty, SYSDATE);
    end if;
END;
CREATE TRIGGER Reorder
AFTER UPDATE OF QtyOnHand OR INSERT ON Inventory
FOR EACH ROW
WHEN (NEW.QtyOnHand < NEW.ThresholdQty)
DECLARE
  N number;
BEGIN
  select count(*) into N
  from PendingOrders
  where Part# = :NEW.Part#;
  If (N==0) then
    insert into PendingOrders(Part#,OrderedQty,OrderDate)
    values (:NEW.Part#, :NEW.ReorderQty, SYSDATE);
  end if;
END;
Concise comparison between Oracle and DB2 Triggers
## Differences between Oracle and DB2

<table>
<thead>
<tr>
<th>Feature</th>
<th>Oracle</th>
<th>DB2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reference to Old_Table and New_Table in statement triggers</td>
<td>No</td>
<td>Yes</td>
</tr>
<tr>
<td>When clause in statement triggers</td>
<td>No</td>
<td>Yes</td>

Database Management Systems

Guidelines in writing triggers in Oracle
Guidelines in writing triggers in Oracle

- Execution Mode INSTEAD OF is allowed in Oracle but it should be avoided.
- Usage of before triggers in Oracle to be compliant with the standard:
  - Modifications of the NEW variable in tuples affected by the triggering statement are allowed in before triggers.
  - Other databases modifications apart those reported in the previous point are not allowed on before triggers.
  - Before triggers cannot trigger other triggers.
Database Management Systems

Trigger Design
The design of a single trigger is usually simple

- Identify
  - execution semantics
  - event
  - condition (optional)
  - action
Understanding *mutual* interactions among triggers is more complex

- The action of one trigger may be the event of a different trigger
  - Cascaded execution

If mutual triggering occurs

- Infinite execution is possible
Trigger execution properties

- **Termination**
  - For an arbitrary database state and user transaction, trigger execution *terminates* in a final state (also after an abort)

- **Confluence**
  - For an arbitrary database state and user transaction, trigger execution *terminates in a unique final state*, independently of the execution order of triggers

- Termination is the most important property
- Confluence is enforced by deterministic trigger execution
Termination is guaranteed at run time by aborting trigger execution after a given cascading length.

Termination may be verified at design time by means of the triggering graph:
- a node for each trigger
- a directed edge $T_i \rightarrow T_j$ if trigger $T_i$ is performing an action triggering trigger $T_j$

A cycle in the graph shows potential non-terminating executions.
Example

- Trigger managing salary amounts
  - When a given average salary value is exceeded, a salary reduction is automatically enforced

- The following table is given

  Employee (Emp#, Ename, ..., Salary)

- Event
  - Update of the Salary attribute in Employee
  - Insert into Employee
    - Will write only trigger for update
Example

- Trigger managing salary amounts
  - When a given average salary value is exceeded, a salary reduction is automatically enforced

- The following table is given
  Employee (Emp#, Ename, ..., Salary)

- Execution semantics
  - After the modification events
  - Separate execution for each update instruction

- No condition for execution
CREATE TRIGGER SalaryMonitor
AFTER UPDATE OF Salary ON Employee
FOR EACH STATEMENT
BEGIN
    update Employee
    set Salary = Salary * K
    where 2500 < (select AVG (Salary) from Employee);
END;

The value of K may be
K = 0.9  →  execution terminates
K = 1.1  →  infinite execution
Trigger applications

- **Internal applications**
  - maintenance of complex integrity constraints
  - replication management
  - materialized view maintenance

- **Business Rules**
  - Incorporate into the DBMS application knowledge
    - E.g., reorder rule

- **Alerters**
  - widely used for notification
Triggers for constraint management

Triggers are exploited to enforce complex integrity constraints

Design procedure

1. Write the constraint as a SQL predicate
   - It provides a condition for the trigger execution
2. Identify the events which may violate the constraint
   - i.e. the condition
3. Define the constraint management technique in the action
The following tables are given

- Supplier $S (S\#, S\text{Name}, \ldots)$
- Part $P (P\#, P\text{Name}, \ldots)$
- Supply $SP (S\#, P\#, Qty)$

Constraint to be enforced

- A part may be supplied by at most 10 different suppliers
Constraint predicate

```
select P#
from SP
group by P#
having count(*) > 10

• set of parts violating the constraint
```

Events

• insert on SP
• update of P# on SP

Action

• reject the violating transaction
Execution semantics

- *after* the modification
- *statement level*
  
  - to capture the effect of the entire modification
  - (Oracle) to allow access to the mutating table

(Oracle) No condition

- The condition cannot be specified in the WHEN clause
- It is checked in the trigger body

Design for Oracle trigger semantics
CREATE TRIGGER TooManySuppliers
AFTER UPDATE OF P# OR INSERT ON SP
DECLARE
  N number;
BEGIN
  select count(*) into N
  from SP
  where P# IN (select P# from SP
                group by P#
                having count(*) > 10);
  if (N <> 0) then
    raise_application_error (xxx, 'constraint violated');
  end if;
END;
The following tables are given

- Supplier $S (S\#, SName, ...)$
- Part $P (P\#, PName, ...)$
- Supply $SP (S\#, P\#, Qty)$

Constraint to be enforced

- The quantity of a product supply cannot be larger than 1000. If it is larger, trim it to 1000.

Check constraints do not allow compensating actions

- Implement with a trigger
Constraint predicate
- Qty > 1000
- It is also the trigger condition

Events
- insert on SP
- update of Qty on SP

Action
- Qty = 1000
Execution semantics

- *before* the modification takes place
  - its effect can be changed before the constraint is checked
- *row level*
  - each tuple is modified separately
CREATE TRIGGER ExcessiveQty
BEFORE UPDATE OF Qty OR INSERT ON SP
FOR EACH ROW
WHEN (NEW.Qty > 1000)
BEGIN
  :NEW.Qty := 1000;
END;
Triggers for materialized view maintenance

- Materialized views are queries persistently stored in the database
  - provide increased performance
  - contain redundant information
    - e.g., aggregate computations

- Triggers are exploited to maintain redundant data
  - Propagate data modifications on tables to materialized view
Tables

- Student \( S \) (SID, SName, DCId)
- Degree course \( DC \) (DCId, DCName)

Materialized view

- Enrolled students \( ES \) (DCId, TotalStudents)
  - For each degree course, TotalStudents counts the total number of enrolled students
  - Defined by query

\[
\text{SELECT DCId, COUNT(*)}
\text{FROM S}
\text{GROUP BY DCId;}
\]
Tables

- Student  $S$ (SI\text{d}, SName, DC\text{i}d)
- Degree course  $DC$ (DC\text{i}d, DC\text{Name})

Materialized view

- Enrolled students  $ES$ (DC\text{i}d, Total\text{Students})
  - For each degree course, Total\text{Students} counts the total number of enrolled students
- A new degree course is inserted in materialized view $ES$ when the first student is enrolled in it
- A degree course is deleted from $ES$ when the last student quits it
Database schema

S (SId, SName, DCId)
DC (DCId, DCName)
ES (DCId, TotalStudents)

Propagate modifications on table S to materialized view (table) ES

- Inserting new tuples into S
- Deleting tuples from S
- Updating the DCId attribute in one or more tuples of S
Design example (3)

- Design three triggers to manage separately each data modification
  - Insert trigger, delete trigger, update trigger
  - All triggers share the same execution semantics

- Execution semantics
  - *after* the modification takes place
    - Table ES is updated after table S has been modified
  - *row level*
    - Separate execution for each tuple of table S
      - significantly simpler to implement
Event
- insert on S

No condition
- It is always executed

Action
- if table ES contains the DCId in which the student is enrolled
  - increment TotalStudents
- otherwise
  - add a new tuple in table ES for the degree course, with TotalStudents set to 1
CREATE TRIGGER InsertNewStudent
AFTER INSERT ON S
FOR EACH ROW
DECLARE
  N number;
BEGIN
  --- check if table ES contains the tuple for the degree
  --- course NEW.DCId in which the student enrolls
  select count(*) into N
  from ES
  where DCId = :NEW. DCId;
if (N <> 0) then
    --- the tuple for the NEW.DCId degree course is
    --- available in ES
    update ES
    set TotalStudents = TotalStudents +1
    where DCId = :NEW.DCId;
else
    --- no tuple for the NEW.DCId degree course is
    --- available in ES
    insert into ES (DCId, TotalStudents)
    values (:NEW.DCId, 1);
end if;
END;
Delete trigger (3)

- Event
  - delete from S
- No condition
  - It is always executed
- Action
  - if the student was the only student enrolled in the degree course
    - delete the corresponding tuple from ES
  - otherwise
    - decrement TotalStudents
CREATE TRIGGER DeleteStudent
AFTER DELETE ON S
FOR EACH ROW
DECLARE
 N number;
BEGIN
    --- read the number of students enrolled on
    --- the degree course OLD.DCId
    select TotalStudents into N
    from ES
    where DCId = :OLD.DCId;
if (N > 1) then
    --- there are many enrolled students
    update ES
    set TotalStudents = TotalStudents – 1
    where DCId = :OLD.DCID;
else
    --- there is a single enrolled student
    delete from ES
    where DCId = :OLD.DCID;
end if;
END;
Event
- Update of DCId on S

No condition
- It is always executed

Action
- update table ES for the degree course where the student was enrolled
  - decrement TotalStudents, or delete tuple if last student
- update table ES for the degree course where the student is currently enrolled
  - increment TotalStudents, or insert new tuple if first student
CREATE TRIGGER UpdateDegreeCourse
AFTER UPDATE OF DCId ON S
FOR EACH ROW
DECLARE
    N number;
BEGIN
    --- read the number of students enrolled in
    --- degree course OLD.DCId
    select TotalStudents into N
    from ES
    where DCId = :OLD.DCId;
if \( N > 1 \) then
--- there are many enrolled students
update ES
set TotalStudents = TotalStudents \(-\) 1
where DCId = :OLD.DCID;
else
--- there is a single enrolled student
delete from ES
where DCId = :OLD.DCID;
end if;
Update trigger (3)

--- check if table ES contains the tuple for the degree course NEW.DCIId in which the student is enrolled

select count(*) into N
from ES
where DCId = :NEW. DCId;
if (N <> 0) then
    --- the tuple for the NEW.DCId degree course is available in ES
    update ES
    set TotalStudents = TotalStudents + 1
    where DCId = :NEW.DCId;
else
    --- no tuple for the NEW.DCId degree course is available in ES
    insert into ES (DCId, TotalStudents)
    values (:NEW.DCId, 1);
end if;
END;
