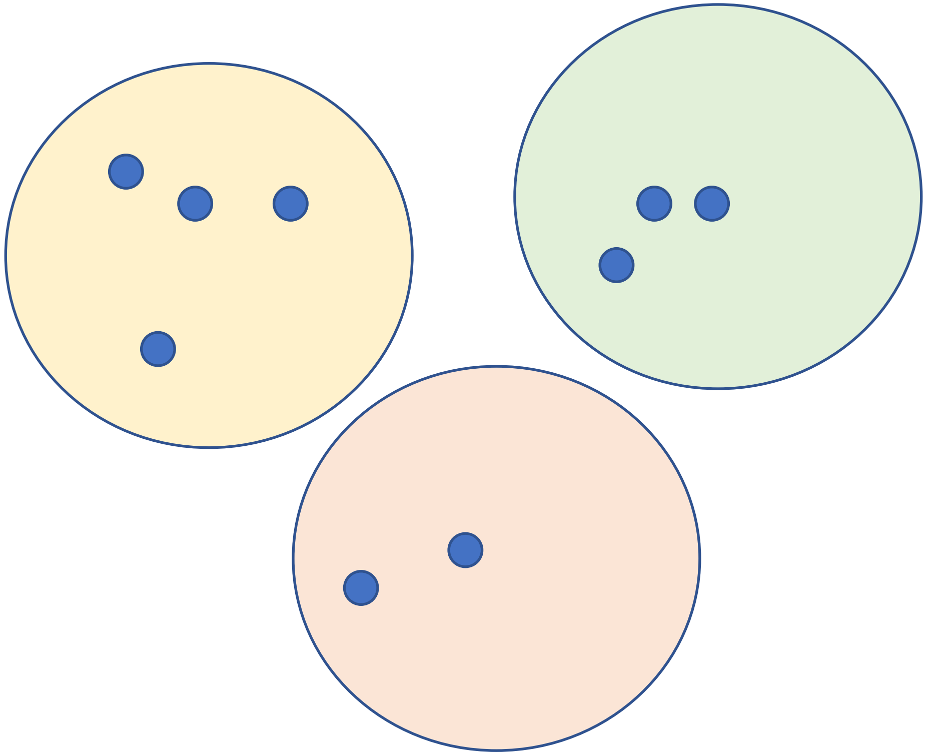
Clustering

DataBase and Data Mining Group

Andrea Pasini, Elena Baralis

Clustering

- **Unsupervised** technique that analyzes the data distribution to generate N partitions
  - Unsupervised = it only requires a features matrix



Clustering

- Import a model

```
from sklearn.cluster import KMeans
```

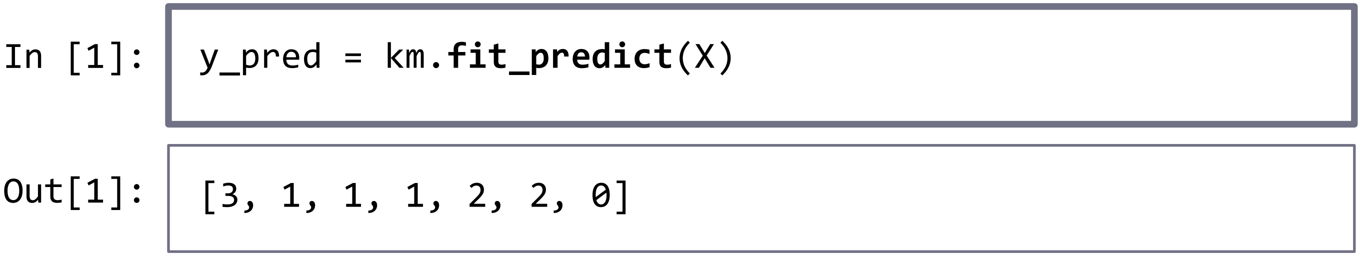
- Build model object

```
km = KMeans(n_clusters = 5)
```

  - The hyperparameter **n_clusters** specifies the number of centroids (= number of clusters)
    - Default is 8 (buy may change across different library versions)

Clustering

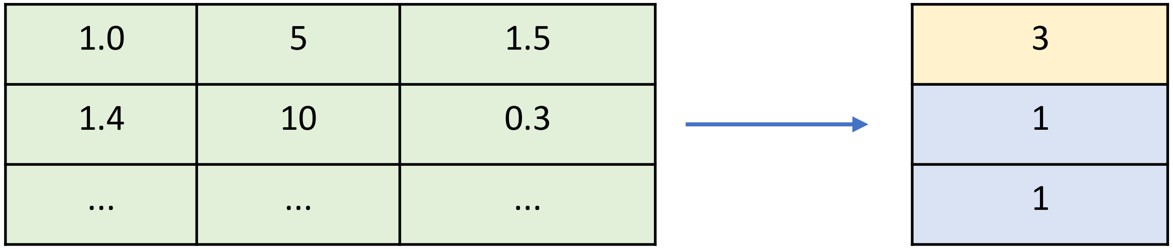
- Apply clustering to input data



```
In [1]:  y_pred = km.fit_predict(X)

Out[1]:  [3, 1, 1, 1, 2, 2, 0]
```

  - This operation assigns data to their respective cluster
    - X is the 2D Numpy array with input features (**features matrix**)
    - y_pred is a 1D array with cluster labels



1.0	5	1.5
1.4	10	0.3
…	…	…

3
1
1

Clustering

- Example: DBSCAN

```
from sklearn.cluster import DBSCAN
cl_alg = DBSCAN(eps=3, min_samples=2)
```

- Example: Hierarchical clustering, n_clusters=5, average linkage

```
from sklearn.cluster import AgglomerativeClustering
cl_alg = AgglomerativeClustering(5, linkage='average')
```

Clustering

- Assessing clustering results
  - **Internal** metrics: use only the information of the features matrix
    - E.g. Silhouette, SSE

```
from sklearn.metrics import silhouette_score, silhouette_samples
silh_avg = silhouette_score(X, clusters)
silh_i = silhouette_samples(X, clusters)
```

  - **Silhouette** is a number in the range [−1, 1]
  - Higher values mean higher cluster quality
    - Cluster that are well separated and compact

Clustering

- Assessing clustering results
  - **External** metrics: compare a clustering result with some ground-truth labels
    - E.g. Adjusted Rand Score, Fowlkes Mallows

```
from sklearn.metrics import adjusted_rand_score
ars = adjusted_rand_score(c_truth, c_pred)
```

  - The ARS score ranges in [0, 1]
  - It is close to 1 when data in the predicted clusters is grouped in a similar way compared with ground truth

Clustering

- Adjusted Rand Score (ARS)
  - Does not check for equality of target and predictions
  - It checks whether data are **clustered in the same way**
  - Example:
    - c_truth = [1, 1, 2, 2, 2, 1]
    - c_pred = [2, 2, 1, 1, 1, 2]
    - ARS(c_truth, c_pred) is 1

Notebook Examples
